

FINNA ACE THIS BIH

Simple Linear Regression

$$\hat{Y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_i + \epsilon_i$$

where \hat{Y}_i are the fitted values, and

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (y_i - \bar{y})(x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{S_{xy}}{S_{xx}}, \quad \hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

β_1 is the change in the mean of Y_i for a 1 unit increase in x_i , β_0 is the mean when $x_i = 0$

$$S_{XX} = \sum (x_i - \bar{x})^2, S_{YY} = \sum (y_i - \bar{y})^2, S_{XY} = \sum (x_i - \bar{x})(y_i - \bar{y})$$

Estimating σ^2

The larger σ^2 , the more dispersed the points will be around the line, i.e. less precise model.

$$1) \text{ Standard deviation of } \hat{\beta}_1: \sigma_{\hat{\beta}_1} = \sqrt{\text{var}(\hat{\beta}_1)} = \sigma / \sqrt{S_{XX}}$$

$$2) \text{ Variance of residuals: } \hat{\sigma}^2 = \frac{1}{n-2} \sum_{i=1}^n (y_i - \hat{y}_i)^2 = \frac{SSE}{n-2}$$

$$3) SSE = S_{YY} - \hat{\beta}_1 S_{XY}$$

$$4) \hat{\sigma}_{\hat{\beta}_1} = \hat{\sigma} / \sqrt{S_{XX}}, \text{ and } S_{XX} = \left(\frac{\hat{\sigma}}{\hat{\sigma}_{\hat{\beta}_1}} \right)^2$$

Inference about β_1

- When the error terms are normal, $\hat{\beta}_1 \sim \mathcal{N}(\beta_1, \sigma^2 / S_{XX})$
- $\mathcal{H}_0 : \beta_1 = 0$ vs $\mathcal{H}_a : \beta_1 \neq 0$

$$T_{obs} = \frac{\hat{\beta}_1}{\hat{\sigma}_{\hat{\beta}_1}} = \frac{\hat{\beta}_1}{\hat{\sigma} / \sqrt{S_{XX}}}, \quad RR = \{T_{obs} > t_{\alpha/2, n-2}\}$$

3) Could get same conclusion from p-value, which illustrates the probability that our results occurred under \mathcal{H}_0 . That is, the probability that $F > \mathcal{F}$ under \mathcal{H}_0 .

$$4) \text{ Confidence interval for } \beta_1: \hat{\beta}_1 \pm t_{n-2, \alpha/2} \frac{\hat{\sigma}}{\sqrt{S_{XX}}}.$$

ANOVA

$$SS_{reg} = S_{YY} - SSE = \sum (y_i - \bar{y})^2 - \sum (y_i - \hat{y}_i)^2 = \sum (\hat{y}_i - \bar{y})^2$$

$$T \sim t_v, \quad T^2 \sim \mathcal{F}(1, v)$$

Source	df	SS	MS	F	p-value
Model	1	SS _{reg}	MST = SS _{reg}	$\frac{MST}{MSE}$	Pr ($F^* > F$)
Error	$n-2$	SSE	MSE = $\frac{SSE}{n-2}$		

lm summary table

- t-value (slope): $T_{obs} = \frac{\hat{\beta}_1}{\hat{\sigma}_{\hat{\beta}_1}}$
- Std error (slope) : $\hat{\sigma}_{\hat{\beta}_1}$
- F-statistic : T_{obs}^2
- Residual std error: $\hat{\sigma}$

Correlation

- corr(X,Y) = corr(Y,X)
- $r = S_{XY} / \sqrt{S_{XX} S_{YY}}$ is an estimator for ρ (the true pop. correlation).
- $(1 - \alpha)100\%$ confidence interval for ρ : transform r to $z = 0.5 \ln\left(\frac{1+r}{1-r}\right)$. Build an interval: $z \pm \frac{z_{\alpha/2}}{\sqrt{n-3}} = (c_l, c_u)$, where $z_{\alpha/2}$ is from the standard Normal table. Then, the interval is $\left(\frac{e^{2c_l} - 1}{e^{2c_l} + 1}, \frac{e^{2c_u} - 1}{e^{2c_u} + 1} \right)$
- Coefficient of determination: $R^2 = 1 - SSE / S_{YY}$

Estimating response

- Mean response confidence interval:
 $\hat{y}_0 \pm t_{n-2, \alpha/2} \hat{\sigma} \sqrt{1/n + (x_0 - \bar{x})^2 / S_{XX}}$
- Individual value Y_0 confidence interval:
 $\hat{y}_0 \pm t_{n-2, \alpha/2} \hat{\sigma} \sqrt{1 + 1/n + (x_0 - \bar{x})^2 / S_{XX}}$

Residual Analysis

We estimate error terms $\epsilon_1, \dots, \epsilon_n$ with residuals $\hat{\epsilon}_1, \dots, \hat{\epsilon}_n$, where $\hat{\epsilon}_i = y_i - \hat{y}_i$. It is recommended that we use the studentized residuals: $\hat{\epsilon}_i^{std} = \hat{\epsilon}_i / \hat{\sigma}$

- Assumptions: ϵ_i are independent, $E(\epsilon_i) = 0$, $\text{var}(\epsilon_i) = \sigma^2$, $\epsilon_i \sim \mathcal{N}(0, \sigma^2)$
- Check Normality with QQ plot and histogram of the studentized residuals, which have mean 0, std dev 1, all residuals should lie within 3 std deviations.
- Check $E(\epsilon_i) = 0$ and $\text{var}(\epsilon_i) = \sigma^2$ (homoscedasticity) by plotting studentized residuals against fitted values. Points should have equal variance and zero mean, i.e. evenly distributed.

Polynomial Regression

$Y_i = \beta_0 + \beta_1 x_i + \beta_2 x_i^2 + \dots + \beta_p x_i^p \epsilon_i$, not all intermediate powers need be present.

Higher-order terms are specified using the $I(\cdot)$ function in R.

- Test that the quadratic term is zero: $H_0 : \beta_2 = 0$.
- If rejected, use linear and quadratic terms in model.
- If not rejected, there is no evidence that the quadratic model gives significant improvement over the linear model.

Multiple Regression (2+ covariates)

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_k x_{ik} + \epsilon_i$$

The model is linear in the parameters (β_i), not necessarily in the covariates (x_i). Same assumptions are made about the residuals.

β_j is the change in the mean of Y_i for a 1 unit increase of x_{ij} after adjusting for all other variables in the model.

- $\hat{\sigma}^2 = (n - (K + 1))^{-1} \sum (y_i - \hat{y}_i)^2 = SSE / (n - (K + 1))$ where $(K+1)$ is the number of coefficients β_i in the model.
- Can test each coefficient individually with same hypothesis as in simple regression. In which case, we test for e.g. β_j after adjusting for all other variables.
- Confidence interval for $\beta_j : \hat{\beta}_j \pm t_{n-(K+1), \alpha/2} \cdot \hat{\sigma} \hat{\beta}_j$
- Global Fit: $R_a^2 = 1 - \frac{n-1}{n-(K+1)} \left(\frac{SSE}{S_{YY}} \right) = 1 - \frac{n-1}{n-K-1} (1 - R^2)$

$$\mathcal{H}_0 : \beta_1 = \beta_2 = \dots = 0 \quad \mathcal{H}_a : \text{at least one } \beta_j \neq 0$$

$$F = \frac{(S_{YY} - SSE) / K}{SSE / (n - (K + 1))} = \frac{R^2 / K}{(1 - R^2) / (n - (K + 1))} = \frac{MSR}{MSE}$$

$$RR = \{F > \mathcal{F}_{\alpha, K, n-(K+1)}\}$$

Interaction

If an interaction is suspected between X_1 and X_2 , we incorporate the interaction by setting $Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i1} x_{i2} + \epsilon_i = \beta_0 + \beta_1 x_{i1} + (\beta_2 + \beta_3 x_{i1}) x_{i2} + \epsilon_i = \beta_0 + (\beta_1 + \beta_3 x_{i2}) x_{i1} + \beta_2 x_{i2} + \epsilon_i$

In the above model, a 1-unit increase in x_2 for a fixed x_1 corresponds to an estimated $\beta_2 + \beta_3 x_1$ increase in Y_i .

- Fit the model including the covariates and interaction.
- Conduct a global F-test with $\mathcal{H}_0 : \beta_1 = \beta_2 = \beta_3 = 0$
- If rejected, test for an interaction by using a Student t-test to test $\mathcal{H}_0 : \beta_3 = 0$. If rejected, stop. Otherwise, re-fit the model without the interaction.

Qualitative

Set $Z_i = 0 \forall i$ for reference group and $Z_i = \begin{cases} 1 & \text{if condition i} \\ 0 & \text{otherwise} \end{cases}$

$$Y_i = \beta_0 + \beta_1 z_1 + \beta_2 z_2 + \epsilon_i$$

Where $\hat{\beta}_0 = \mu_0$, $\hat{\beta}_1 = \mu_1 - \mu_0$, and $\hat{\beta}_2 = \mu_2 - \mu_0$, and $\mathcal{H}_0 : \beta_1 = \beta_2 = 0 \iff \mathcal{H}_0 : \mu_2 = \mu_1 = \mu_0$, $\mathcal{H}_a : \geq 1 \beta_i \neq 0$

Qualitative and quantitative:

The model is $Y_i = \beta_0 + \beta_1 z_i + \beta_2 x_i$.

- $z_i = 0$: $Y_i = \beta_0 + \beta_2 x_i$
- $z_i = 1$: $Y_i = \beta_0 + \beta_1 + \beta_2 x_i$

So the slope is the same, only y-intercept changes.

Interaction: $Y_i = \beta_0 + \beta_1 z_i + \beta_2 x_i + \beta_3 z_1 x_i$. Then, slopes vary:

- $z_i = 0$: $Y_i = \beta_0 + \beta_2 x_i$
- $z_i = 1$: $Y_i = \beta_0 + \beta_1 + (\beta_2 + \beta_3) x_i$

Where $\beta_1 + \beta_3 x_i$ is the difference in Y between $z_i = 1$ and $z_i = 0$. Should always test for existence of an interaction. If no evidence to reject \mathcal{H}_0 of no interaction, must re-fit model without interaction. If evidence of interaction, slopes are different and interpret the results accordingly.

Comparing Nested Models

M_0 and M_1 are nested models if one contains a subset of the other.

$$M_0 = \beta_0 + \dots + \beta_g x_g, M_1 = M_0 + \beta_{g+1} x_{g+1} + \dots + \beta_k x_k$$

$$\mathcal{H}_0 : \beta_{g+1} x_{g+1} = \dots = \beta_k x_k = 0 \quad \mathcal{H}_a : \text{at least 1 } \beta_i \neq 0$$

Note: we always have $SSE_{M_0} \geq SSE_{M_1}$.

- $SSE_{M_0} - SSE_{M_1}$ large $\implies M_1$ explains more variance than just using M_0 .
- $SSE_{M_0} - SSE_{M_1}$ small \implies additional terms in M_1 don't contribute to model fit.

To determine how "large" the difference is:

$$F = \frac{(SSE_{M_0} - SSE_{M_1}) / (k - g)}{SSE_{M_1} / (n - (k + 1))}, \quad RR = \{F > \mathcal{F}(\alpha, k - g, n - (k + 1))\}$$

Multicollinearity

When two covariates in a regression analysis are highly correlated with each other. The covariates "compete" for the explanatory power in the association with the response.

Multinomial Distribution

One qualitative variable C can take k possible values $\{c_1, \dots, c_k\}$. Let X_i the # of times c_i occurs. The set of X_i has a multinomial distribution.

$$P(X_1 = n_1, \dots, X_k = n_k) = \frac{n!}{n_1! \dots n_k!} p_1^{n_1} \dots p_k^{n_k}$$

where $n_1 + \dots + n_k = n$. $E(X_i) = np_i$.

Chi-square

$\mathcal{H}_0 : p_1 = p_1^*, \dots, p_k = p_k^* \quad \mathcal{H}_a : p_i \neq p_i^*$ for at least one i

Given by Pearson's chi-square statistic :

$$X_{obs}^2 = \sum_{i=1}^k \frac{(n_i - np_i^*)^2}{np_i^*} = \sum_{i=1}^k \frac{(O_i - E_i)^2}{E_i}$$

Where O_i :=observed and E_i :=expected. Distribution of χ^2 under \mathcal{H}_0 is $\chi_{(k-1)}^2$, $(k-1)$:=(deg. of freedom). Given α ,

$RR = \{X_{obs}^2 > \chi_{\alpha, (k-1)}^2\}$ and $p = Pr\{\chi_{(k-1)}^2 > X_{obs}^2\}$. Every expected count must be ≥ 5 for this test.

Contingency tables

Y/X	1	2	...	c	Total
1	n_{11}	n_{12}	...	n_{1c}	$n_{1\bullet}$
2	n_{21}	n_{22}	...	n_{2c}	$n_{2\bullet}$
.
.
r	n_{r1}	n_{r2}	...	n_{rc}	$n_{r\bullet}$
Total	$n_{\bullet 1}$	$n_{\bullet 2}$...	$n_{\bullet c}$	n

$$n_{j\bullet} = n_{j1} + \dots + n_{jc}, n_{\bullet k} = n_{1k} + \dots + n_{rk}.$$

$$n_{1\bullet} + \dots + n_{r\bullet} = n_{\bullet 1} + \dots + n_{\bullet c} = n \text{ (sum of all entries).}$$

We want to test :

$\mathcal{H}_0 : X, Y$ independent vs $\mathcal{H}_a : X, Y$ not independent. The expected counts are given by $\hat{E}_{jk} = n \hat{p}_{j\bullet} \hat{p}_{\bullet k} = n_{j\bullet} n_{\bullet k} / n$, where $\hat{p}_{j\bullet} = n_{j\bullet} / n$, $\hat{p}_{\bullet k} = n_{\bullet k} / n$

$$X^2 = \sum_{j=1}^r \sum_{k=1}^c \frac{(n_{jk} - \hat{E}_{jk})^2}{\hat{E}_{jk}}, \quad RR = \{X^2 > \chi_{\alpha, (r-1)(c-1)}^2\}$$

Must have expected cell count ≥ 5 for all cells, observations must be mutually independent and identically distributed.

Fisher's exact test

If expected cell count is not ≥ 5 for all cells.

McNemar's test

Matched pairs experiments, e.g.

Response 1/2	Yes	No	Total
Yes	n_{11}	n_{12}	$n_{1\bullet}$
No	n_{21}	n_{22}	$n_{2\bullet}$
Total	$n_{\bullet 1}$	$n_{\bullet 2}$	n

Want to test whether the proportions are the same in both responses, i.e. $\mathcal{H}_0 : p_1 = p_2$, $\mathcal{H}_a : p_1 \neq p_2$.

$$Q_M = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}, \quad RR = \{Q_M > \chi_{\alpha, 1}^2\}$$

Non-Parametric statistics

Wilcoxon test

To test the hypothesis that the probability distributions of both pop. are equivalent ($D_0 = D_1$).

Conditions: independent samples, cts distributions.

- 1) order together the observations from both samples
- 2) assign a rank to each, if equality, take average of ranks.
- 3) take sum of ranks of each group, let T the sum of sample with smaller size.

$\mathcal{H}_0 : D_0 = D_1, \mathcal{H}_a : (T_U, T_L \text{ are table values}),$

- 1) D_1 left of D_2 : $RR = \{T \leq T_L\}$ if $T = T_1, \{T \geq T_U\}$ o.w.
- 2) D_1 right of D_2 : $RR = \{T \geq T_U\}$ if $T = T_1, \{T \leq T_L\}$ o.w.
- 3) D_1 either left or right of D_2 : $RR = \{T \leq T_L \text{ or } T \geq T_U\}$.

Normal approx. of Wilcoxon

If $n_1, n_2 \geq 10$. $Z = \frac{T_1 - (n_1(n_1 + n_2 + 1)/2)}{\sqrt{n_1 n_2 (n_1 + n_2 + 1)/12}}$, where T_1 sum of ranks

corresponding to D_1, n_i sample size. Then, $Z \sim \mathcal{N}(0, 1)$ and, letting z_α the value from normal table:

- (1) $RR = \{Z < -z_\alpha\}; p\text{-value} = Pr(Z < Z_{obs})$
- (2) $RR = \{Z > z_\alpha\}; p\text{-value} = Pr(Z > Z_{obs})$
- (3) $RR = \{|Z| > z_{\alpha/2}\}; p\text{-value} = 2 \times Pr(Z > |Z_{obs}|)$

Wilcoxon's signed rank test (for paired data)

Let $X_1, \dots, X_n, Y_1, \dots, Y_n$ random samples of paired observations. $Diff_1 = X_1 - Y_1, \dots, Diff_n = X_n - Y_n$. Don't need normality of the differences.

- 1) order absolute values of differences, take out the zeros
- 2) rank the differences, ties handled as usual
- 3) let T_+, T_- sum of ranks of positive and negative differences

$\mathcal{H}_0 : D_1 = D_2, \mathcal{H}_a$: same as before, with T_0 table value:

- 1) $RR = \{T_+ \leq T_0\}$ 2) $RR = \{T_- \leq T_0\}$
- 3) $RR = \{T \leq T_0\}$ where $T =$ the smallest of T_-, T_+

Note: in the table values, n is the number of differences left after removal of the zeros.

Large sample Wilcoxon's signed rank test

If the number of pairs $n \geq 25$ (after excluding zeros), then

$$Z = \frac{T_+ - (n(n+1)/4)}{\sqrt{n(n+1)(2n+1)/24}}, Z \sim \mathcal{N}(0, 1), RR \text{ same as 2 sections above.}$$

Kruskal-Wallis test (CRD)

Def. (CRD): treatments are assigned randomly so that each experimental unit gets the same chance of receiving any one treatment. KW: Rank-based non-parametric test to test difference in distribution among ≥ 2 groups. Conditions: the K samples are random and independent, 5 or more measurements in each sample, the K probability distributions from which the samples are drawn are continuous. \mathcal{H}_0 : the k distributions are identical, \mathcal{H}_a : at least one differs.

- 1) Take ranks of observations, as if they belonged to the same group.
 - 2) Let \bar{R}_j be the rank average of group $j, \bar{R} = (n+1)/2$ the overall avg.
- Under \mathcal{H}_0 , we expect $\bar{R}_1 \approx \dots \approx \bar{R}_K$.

$$KW = \frac{12}{n(n+1)} \sum_{j=1}^k n_j (\bar{R}_j - \bar{R})^2 \quad RR = \{KW > \chi^2_{\alpha, k-1}\}$$

Friedman test (RBD)

A matched set of B blocks are formed with each consisting of K experimental units. One experimental unit from each block is randomly assigned to each treatment. Special case: We have B subjects, each receives all K treatments. Each subject is a block and the experimental units are the repeat assessments on the same subject. Note: We should not give the subjects each treatment in the same order.

Condition: B or $K \geq 5$

- 1) Rank the observations within blocks.
- 2) \bar{R}_j average of ranks within treatment j .

Total average of ranks is $K(K+1)/2$, under \mathcal{H}_0 , we expect

$$\bar{R}_1 \approx \dots \approx \bar{R}_K.$$

$$F_r = \frac{12B}{K(K+1)} \sum_{j=1}^K (\bar{R}_j - \bar{R})^2 \quad RR = \{F_r > \chi^2_{\alpha, K-1}\}$$

Spearman's rank correlation coefficient

Consider n mutually indep. and identically distributed pairs of variables $(X_1, Y_1), \dots, (X_n, Y_n)$.

- 1) Rank the observations within $X : u_i$ and $Y : v_i$

- 2) if no ties in both, $r_s = 1 - \frac{6}{n(n^2-1)} \sum_{i=1}^n (v_i - u_i)^2$

- 3) else, $r_s = \frac{SS_{uv}}{\sqrt{SS_{uu}SS_{vv}}}$, where $SS_{uv} = \sum (u_i - \bar{u})(v_i - \bar{v})$

A confidence interval for ρ is built the same way as earlier.

ANOVA

To test the equality of means in K populations.

$\mathcal{H}_0 : \mu_1 = \dots = \mu_K = \mu, \mathcal{H}_a$: at least one differs. Assume homoscedasticity ($\sigma_1^2 = \dots = \sigma_K^2$), normally distributed response. Let $\bar{Y}_k = 1/n_k (Y_{k1} + \dots + Y_{kn_k}) = \hat{\mu}_k, \hat{\mu} = \bar{Y}$.

$SSE = \sum_{k=1}^K \sum_{i=1}^{n_k} (Y_{ki} - \bar{Y}_k)^2 = \sum_{k=1}^K (n_k - 1)S_k^2$, where S_k^2 the sample variance in group $k, SST = \sum_{k=1}^K n_k (\hat{\mu}_k - \hat{\mu})^2$.

$$F = \frac{MST}{MSE} = \frac{SST/(K-1)}{SSE/(n-K)}, \quad RR = \{F > \mathcal{F}_{\alpha, K-1, n-K}\}$$

Source	df	SS	MS	F	p-value
Treat	$K - 1$	SST	MST	$\frac{MST}{MSE}$	$P(\mathcal{F}_{K-1, n-K} > F)$
Error	$n - K$	SSE	MSE		
Total	$n - 1$	$SS_{tot} = SSE + SST$			

Comparing means

Student t-test for means

Estimates the true difference between two group means. $100(1 - \alpha)\%$ CI for the mean difference:

$$(\bar{Y}_i - \bar{Y}_j) \pm t_{\alpha/2, n_i + n_j - 2} \sqrt{S_p^2/n_i + S_p^2/n_j}$$

where $S_p^2 = \frac{(n_i - 1)S_i^2 + (n_j - 1)S_j^2}{n_i + n_j}$ is the pooled variance.

Multiple comparisons

Want to compare differences between groups two at a time to see how different they are. Assume equal var, normality. Conf. int for diff. in means: $(\bar{Y}_i - \bar{Y}_j) \pm t_{(\alpha/2, n-K)} \sqrt{MSE/n_i + MSE/n_j}$

Bonferroni: if we want an experiment-wise error α_E , then should take comparison-wise error α_E/C where C is the # of comparisons. Turkey's HSD: all groups of equal size, only pair-wise comp. Scheffe's: for linear comb. of means : $\mu_1 + \mu_2 - \mu_3$

ANOVA for RBD

Note: SST and SS_{Tot} stay the same whether the blocks are included or not.

Source	df	SS	MS	F
Treat	$K - 1$	SST	MST = $\frac{SST}{K-1}$	$\frac{MST}{MSE}$
Blocks	$B - 1$	SSB	MSB = $\frac{SSB}{B-1}$	$\frac{MSB}{MSE}$
Error	$n - K - B + 1$	SSE	MSE = $\frac{SSE}{n-K-B+1}$	
Total	$n - 1$	SS_{Tot}		

Anova F -test (treat) : $\mathcal{H}_0 : \mu_1 = \dots = \mu_k, \mathcal{H}_a : \geq 1$ differs.

$$F = \frac{SST/(K-1)}{SSE/(n-K-B+1)} = \frac{MST}{MSE}, RR = \{F > \mathcal{F}_{\alpha, K-1, n-K-B+1}\}$$

Anova F -test (block) : same as above, but with the means within blocks. Replace SST with SSB, $(K - 1)$ with $(B - 1)$. SSB is the same as SST, but within blocks. If \mathcal{H}_0 rejected, proceed with MC of means.

2-way ANOVA

To explore effect of two factors A and B on a response variable. A: J levels, B: K levels. R replications for each of the $J \times K$ combinations: total observations is $n = J \times K \times R$. Let Y_{jkr} the response val. for factors A: lvl j, B : lvl k , replication r . That is, r^{th} rep. within treat. (j, k)

- 1) test interaction between A & B. If \mathcal{H}_0 : no interaction is rejected: use MC to compare pairs of treatments.

- 2) else test for main effect of A (resp. B). If evidence of main effect, use MC for pairs within A (resp. B) only.

$$SST = R \sum_{j=1}^J \sum_{k=1}^K (\bar{Y}_{jk\bullet} - \bar{Y})^2, SSA = RK \sum_{j=1}^J (\bar{Y}_{j\bullet\bullet} - \bar{Y})^2,$$

$$SSB = RJ \sum_{k=1}^K (\bar{Y}_{\bullet k\bullet} - \bar{Y})^2, SS(AB) = SST - SSA - SSB, \text{ where } \bar{Y} \text{ the overall mean.}$$

The sample variance for (j, k) is

$$S_{jk}^2 = \frac{1}{R-1} \sum_{r=1}^R (Y_{jkr} - \bar{Y}_{jk\bullet})^2,$$

$$SSE = \sum_{j,k,r=1}^{J,K,R} (Y_{jkr} - \bar{Y}_{jk\bullet})^2 = (R-1) \sum_{j,k=1}^{J,K} S_{jk}^2$$

Source	df	SS	MS	F
A	$J - 1$	SSA	MSA = $\frac{SSA}{J-1}$	$\frac{MSA}{MSE}$
B	$K - 1$	SSB	MSB = $\frac{SSB}{B-1}$	$\frac{MSB}{MSE}$
AB	$(J-1)(K-1)$	$SS(AB)$	$\frac{SS(AB)}{(J-1)(K-1)}$	$\frac{MS(AB)}{MSE}$
Error	$n - JK$	SSE	MSE = $\frac{SSE}{n-JK}$	
Total	$n - 1$	SS_{Tot}		

Interaction

\mathcal{H}_0 : Factors A and B don't interact, \mathcal{H}_a : they do.

$$F = \frac{MS(AB)}{MSE}, \quad RR = \{F > \mathcal{F}_{\alpha, (J-1)(K-1), n-JK}\}$$

Main effect

If \mathcal{H}_0 of no interaction is not rejected. \mathcal{H}_0 : No difference among the J population mean responses due to factor A, \mathcal{H}_a : At least two of the means differ

$$F = \frac{SSA/(J-1)}{SSE/(n-JK)} = \frac{MSA}{MSE}, \quad RR = \{F > \mathcal{F}_{\alpha, J-1, n-JK}\}$$

Conditions for all ANOVA tests

- 1) Random and independent samples of experimental units are associated with each treatment.
- 2) The probability distribution of responses for each JK factor-level combination (treatment) is approximately Normal.
- 3) The JK factor-level combination (treatment) probability distributions have equal variances.

Steps for HT on Final

- 1) Hypotheses clearly defined. Including explanation of the parameters involved.

- 2) Observed test statistics:

If not provided in an output: Show the complete work used to get the value.

If provided in an output: only write the number E.g. $F_{obs} = \dots$

- 3) If no p-value is provided: Compute a Rejection Region.

Write it clearly as a region. Clearly specify the alpha, df, etc. and the final table value.

If a p-value is provided in an output: only write the p-value.

- 4) Decision: say whether or not you reject H_0 , and mention the alpha.

Justify the decision:

If the decision is taken from a computed RR, then say it:

E.g. Since $F_{obs} = 14.3 > 4.46$ then ...

If a p-value is provided from an output, then say it:

E.g. Since $p\text{-value} = \dots > \alpha$ then ...

- 5) Conclusion.

Write a conclusion in the context of the question. No more than 2 sentences.
